Introduction

We present an ink-jet printing technique that allows precise micropatterning of cell adhesion substrates. Compared with traditional photolithography or recent soft lithographic techniques like PDMS stamping, our ink-jet method allows faster and less expensive fabrication of new patterns.

Disassociated rat hippocampal culture grown at low densities on our inkjet-printed surfaces show:

• Excellent adherence to the pattern over extended time periods
• Normal electrophysiological properties
• Similar distributions of immocytochemical markers for synapses and inhibitory cells as found in unpatterned, low-density controls

Background

• Patterned cell culture can be used to study small, isolated networks, developmental cues, or single cell properties.
• Previous patterning work, such as photolithography (Kleinfeld 1988, Wyart 2001), microcontact printing (Wheeler et al., 1999), laser ablation (Corey et al., 1991) and other methods (Martinioa et al., 1999), relies upon an unalterable master pattern. We use inkjet printing, as it is a programmable and more flexible technique to rapidly print different patterns with minimal expense and time investment.

Patterning

• The flexible surface chemistry allows for printing in either positive or negative relief. This flexibility is possible because the adhesion and repulsion molecules have the same functional/reactive group.

Methods

Diagram of the operation of the ink-jet printer. A pressure impulse delivered by a piezo crystal ejects single droplets by computer control as the print head is moved over the substrate.

The printer is mounted onto a cart for easy mobility.

The printer is mounted onto a cart for easy mobility.

Printed patterns can include micro-islands (left) and connected micro-islands and arbitrary shapes (middle and right).

Results

Patterned cultures show a lower percentage of inhibitory cells (25%) than low-density control cultures (33%) but are not significantly different (p<0.05).

• Immunostain for inhibitory cells (GABA):

Synaptic density is not significantly different (p<0.05) between patterned cultures (2.95 synapses/20um2) and low-density control cultures (2.29 synapses/20um2).

• Immunostain for excitatory and inhibitory synapses (Synapsin I):

FUTURE WORK: Gradients of laminin for developmental study of axon guidance. Linear gradient (left) and circular gradient (right) shown by laminin immunostain adjacent to CAD software representation.

Summary

• We designed an ink-jet printer to programmably arrange chemical factors.
• Patterned neurons exhibited:
  — healthy electrophysiological properties
  — spontaneous activity
  — adherence to patterns for extended periods of time
  — normal immunocytochemical characteristics
• The ability to print gradients and other shapes suggest the use of ink-jet printing for further studies in neuron-substrate interaction and arrangement of neural circuits.
